A new genus of Candoninae (Crustacea, Ostracoda, Candonidae) from the subterranean waters of southwestern Western Australia

Ivana Karanovic
Western Australian Museum, Francis Street, Perth, Western Australia 6000, Australia

Abstract - A new ostracod genus, Acandona gen. nov., is described from subterranean waters of south-western Western Australia. Unlike other Australian Candoninae, it shows great similarities with some Holarctic genera, especially with the genus Pseudocandona Kaufmann, 1900. The two species known are described: Acandona admiratio sp. novo and A. memoria sp. novo. The first species is characterized by the presence of "If" and "Tg" setae on the penultimate segment of the cleaning leg. The latter species lacks the "If" seta, but has a variable number of setae (two or three) on the basal segment of the same leg. Both new species have a characteristic hemipenis, which clearly separates them from other known Candoninae species.

INTRODUCTION

Recent investigations in Western Australia have led to an unprecedented discovery of a biodiverse subterranean biota, comprising numerous short range endemic taxa. Amongst these findings is a rich ground water fauna (stygofauna), many taxa of which have been described in the last decade (Poore and Humphreys, 1992; 1988; Wilson and Ponder, 1992; Bartsch, 1993; Humphreys, 1993a; 1993b; 1993c; 2001; Bruce & Humphreys, 1993; Harvey et al., 1993; Baltanas and Danielopol; 1995; Pesce et al., 1996a; 1996b; Pesce and De Laurentis, 1996; Yager and Humphreys, 1996; Bradbury and Williams, 1996a; 1996b; 1997a; 1997b; Harvey, 1998; De Laurentis et al., 1999; 2001; Knott and Halse, 1999; Watts and Humphreys, 1999; 2000; 2002; in press; Wouters, 1999; Bradbury, 2000; 2002; Danielopol et al., 2000; Jaume and Humphreys, 2001; Jaume et al., 2001; Karanovic et al., 2001; Karanovic and Pesce, 2002; Lee and Huys, 2002).

Ostracods, almost exclusively of the subfamily Candoninae Kaufmann, 1900, are a very important component of any subterranean fauna. Karanovic and Marmonier (2002, in press) described three new genera and 14 new species of Candoninae from subterranean waters of Western Australia making a total of 22 living genera in the subfamily (Karanovic and Marmonier, in press). The following genera are restricted to subtropical and tropical regions: Terrestricandona Danielopol and Betch, 1980; Caribecandona Broodbakker, 1983; Cubacandona Broodbakker, 1983; Danielocandona Broodbakker, 1983; Indocandona Gupta, 1984; Namibcypris Martens, 1992 and Meischcandona Karanovic, 2001. Other than the recently described genera (Karanovic and Marmonier, in press) plus Terrestricandona, Caribecandona and Danielocandona, the other genera restricted to the tropics and subtropics are monospecific, probably as a result of the paucity of research in groundwater to which Candoninae are largely restricted in tropical and subtropical areas. Further research on the biodiversity of subterranean life of those regions will probably lead to the discovery of more new Candoninae species and new genera. The remaining 12 genera of Candoninae are distributed mainly in the Holarctic, although some do have a wider distribution. Among these 12 genera only Phreatocandona Danielopol, 1978 and Paracandona Hirtwig, 1899 have but one living species, the remaining genera being more speciose. In order of species richness these are Pseudocandona Kaufmann, 1900 (about 75 species); Candona Baird, 1845 (ca. 45 recent species); Baicalocandona Mazepova, 1976 (ca. 30 species); Candonopsis Vavra, 1900 (ca. 12 species each); Schellencandona Meisch, 1996; (five recent species); Namocandona Ekman, 1914 and Trajancandona Karanovic, 1999a (two species each) (Meisch, 1996; Karanovic and Marmonier, 2002).

The taxonomy of the subfamily is based on the morphological features of the carapace and soft parts. The main characteristic that unites all 22 genera within the same subfamily is the absence of the swimming setae on the antenna. The appearance of the male's copulatory organ is important for generic discrimination. Because some species reproduce exclusively
parthenogenetically, this organ is unknown and so the generic position of such species is still uncertain. In addition, most species, mainly in the genus *Candona*, were described decades ago and insufficiently for current generic determination because many new characters have been introduced into generic diagnoses. The first serious attempt towards the revision of the subfamily was made by Meisch (1996), who tried to distinguish several European genera according to the appearance of cleaning leg. However, considerably more work needs to be done to understand the zoogeography and evolution of the subfamily *Candoninae*.

In this paper another new genus of *Candoninae*, containing two new species, is described from the subterranean waters of Western Australia.

**MATERIAL AND METHODS**

Samples were collected with haul-nets (mesh sizes from 250 or 350 micrometers) from subterranean water monitoring bores (Yilgarn site) and with hand-nets from caves (Margaret River sites).

Haul-nets are simple plankton nets of a size suitable for the bore, which can range from 30 to 180 mm in diameter. Weighed nets were lowered down into the bore with one bottle screwed on its distal part and hauled through the water column, usually a number of times. From caves samples were taken by sweeping with hand nets (15-20 cm diameter) through pools, including submerged tree roots.

All samples were sorted while alive under dissecting microscope and the ostracods were then fixed in 75% ethanol and assigned a field number (Prefix BES for Yilgarn site; CW for Margaret River sites).

Ostracods were dissected in a mixture of distilled water and glycerol (1:1) with fine entomological needles (mark 000). Dissected appendages and valves of some specimens were fixed in 75% ethanol and assigned a field number (Prefix BES for Yilgarn site; CW for Margaret River sites).

All non-dissected material is preserved in 75% ethanol in glass test-tubes. Drawings have been prepared using a drawing tube attachment on Leica-DMLS brightfield compound microscope, with C-PLAN achromatic objectives.

In the systematic part of this paper the length (L) of all segments was measured in the middle of the segments, and length ratios are presented beginning with the proximal end. All appendages are named according to Martens (1998). The chaetotaxy of all limbs follows the model proposed by Broodbakker & Danielopol (1982), revised for the antenna by Martens (1987), and for the third thoracic leg by Meisch (1996). Lobes on hemipenis are labelled according to Danielopol (1969).

Abbreviations used in the text and figure legends:
- a1 and a2 - lateral (or outer) lobes on hemipenis;
- A1 - antennula; A2 - antenna; b - medial lobe on hemipenis; BES and CW- prefixes for the field numbers; e - bursa copulatrix; d1, d2, dp - setae on basal segment T3; Fu - furca; g - "M" process (middle chitinous part) of hemipenis; G1, G2, G3, GM, Gm - antennal claws; H - height; h - inner lobe on hemipenis; L - length; LV - left valve; Md - mandible; Mxl -Maxillula; RV - right valve; Ta, Tb, Td - setae on T1; Te, Tg, Th1, Th2, Th3 - setae on endopodal segments T3; T1, T2, T3 - first, second and third thoracopods; t1, t2, t3, t4 - setae on the third endopodal segment A2; W - width; WAM - Western Australian Museum; Y, ya, y1, y2, y3 - aesthetasc; z1, z2, z3 - apical setae on the second endopodal segment A2.

**SYSTEMATICS**

Family *Candonidae* Kaufmann, 1900

Subfamily *Candoninae* Kaufmann, 1900

Genus *Acandona* gen. nov.

**Diagnosis**

Carapace subtriangular to triangular. LV overlaps RV dorsally with flange. Valves asymmetrical. Valve surface smooth. A1 seven-segmented. Male's A2 with developed sexual bristles. Exopodite of same appendage with two short and one long seta. Md palp with 3+2 setae in bunch on second segment, same segment externally with two setae; penultimate segment with three setae externally, and four setae distally to intero-distally; gamma seta being smooth. Terminal segment with central claw fused with segment, which squarish. Mxl palp with rectangular terminal segment and same segment with six appendages (two claw-like; four seta-like). Male's prehensile palps strongly asymmetrical, right one being robust; both palps with two subterminal sclerotized structures well developed. Exopodite of T1 with two setae. Same appendage with one "Ta" seta present on protopodite as well as "Tb" and "Td" setae. T2 five segmented; basal segment with seta. T3 limb five segmented; basal segment with all three setae, or seta "d2" missing. Penultimate segment clearly divided, and with "Tf" seta present or absent; terminal segment with setae "Th2" and "Th3" long, while seta "Th1" short. Fu with all setae and claws developed. Hemipenis with lateral shield subdivided into two lobes, "a1" triangular and extended from rest of hemipenis's parts, while "a2" rounded. "M"-process very weakly sclerotized. Lobes "b" and
A new genus of Candoninae

"h" present. Zenker’s organ with seven rows of spines.

**Type species**
*Acandona admiratio* sp. nov.

**Other species**
*Acandona memoria* sp. nov.

**Etymology**
The generic name consists of the first alphabet letter “A” and the genus name *Candona*. Gender feminine.

**Description**

*Male (holotype).* L of LV 0.673 mm, H situated in middle and equalling 49.8% of L. RV being smaller and 0.65 mm long, with greatest H as well in middle and equalling 44.5% of L. Carapace in lateral view (Figure 1A) triangular. Doral margin arched, inclined towards frontal, while rounded towards caudal margin. Both caudal and frontal margins rounded, frontal being wider than caudal one. Ventral margin slightly concave around middle. LV overlaps right one with clear flange dorsally, while

RV overlaps left one, with pronounced selvage, on small patch postero-ventrally. Marginal zone wider anteriorly (20% of L) than posteriorly (10% of L). Marginal pore canals small and straight. Selvage peripheral. In dorsal view (Figure 1B) carapace frontally cuneiform and narrower than caudally. LV clearly overlaps right one on both ends. Greatest W around middle equaling 34% of L. Surface of carapace smooth and hairy.

A1 seven-segmented (Figure 3C). First segment with two setae anteriorly: proximal reaching distal margin of second segment (not shown on figure), distal reaching only middle of same segment. Same segment with two setae posteriorly (almost reaching distal end of fifth segment). Second segment with one seta anteriorly which reaching distal end of fourth segment. Third segment without any seta. Fourth segment with two very long setae anteriorly, and one shorter posteriorly (reaching middle of penultimate segment). Fifth segment with two long setae anteriorly, and one shorter posteriorly (only slightly exceeding distal end of same segment). Penultimate segment with two long setae, and two shorter ones (reaching distal end of terminal...

segment) anteriorly, while same segment posteriorly carries one seta which exceeds distal end of terminal segment. Terminal segment with two long setae, one short (1.7 times longer than segment), and aesthetasc (ya) which 4.2 times longer than terminal segment. All five terminal segments of about same L.

A2 five-segmented (Figure 3B). Exopodite plate with one long seta and two shorter ones. Aesthetasc Y equals 54% of first endopodal segment; y1 slightly exceeds distal end of third segment; y2 about two times as long as terminal segment; y3 six times as long as same segment. First endopodal segment postero-distally with two unequal setae: one reaching middle of terminal claws, other distal end of third segment. Male’s bristles present. Penultimate segment with three long claws (G2 and two transformed setae – z1 and z2), subequally long (1.1 times as long as first endopodal segment). Penultimate segment with two smaller claws (G1 and G3) both being four times as long as terminal segment, and one short seta (z3) (2.5 times as long...
as terminal segment). Terminal segment with long GM claw which 0.9 times as long as first endopodal segment, and small Gm claw two times as long as terminal segment. L : W of terminal segment 1 : 1. L ratios of three distal segments 1.7 : 2.4 : 1.

Md (Figure 3A). Coxa with about eight terminal teeth. Palp 4-segmented. First segment with two long setae (pappose – S1), and two short (pappose – S2). Second segment with two setae externally (reaching middle of following segment), while internally with 3+2 setae in bunch. Penultimate segment with three setae externally, and four distally to intero-distally. Gamma seta smooth. Terminal segment with fused claw which distally pappose. On external side of claw one strong, more claw-like seta, while on internal side two thin setae present. L : W of terminal segment 1 : 1. L ratios of four endopodal segments 8.5 : 3.2 : 2 : 1.

Mxl palp (Figure 3E) with penultimate segment which distally with four pappose setae. Terminal segment rectangular with two claws and four setae.

Prehensile palps on T1 asymmetrical: right one (Figure 2C) more robust than left one (Figure 2B). On both palps main body robust, fingers stocky. On both palps subterminal sclerotized structures elongated. Exopodite consists of two unequal setae. Protopodite with one “Ta” seta. Setae “Tb” and “Td” also present.
A new genus of Candoninae

T2 (Figure 4A) 5-segmented. Basal segment with one seta. First and second endopodal segments with one seta each, penultimate segment with two setae. Terminal segment with two setae and claw which distally strongly serrated and 1.3 times as long as three distal segments combined.

T3 (Figure 4B) 5-segmented. Basal segment with only two setae (d1 and dp). First endopodal segment without any seta, penultimate segment clearly divided and with both "Tf" and "Tg" setae present. Terminal segment with three unequally long setae, "Th" being 1.7 times as long as terminal segment. L ratios of three setae as follows 4.2 : 3 : 1.

Fu (Figure 4C) with both furcal claws and setae developed. Anterior claw slightly longer than posterior one, both claws serrated. Posterior furcal margin with short, stiff setae. L ratios of anterior furcal margin, anterior, and posterior claws 1.5 : 1.1 : 1. Posterior seta reaching distal end of posterior furcal margin. Furcal attachment shown on Figure 4D.

Hemipenis (Figure 2A) robust, with lobe "a1" triangular and extended, "a2" rounded, lobe "h" not evenly rounded, but more wavy, while lobe "b" widely rounded.

Zenker’s organ with seven rows of spines.

Female (allotype). L of LV (Figure 5A) equals 0.6 mm, with greatest H around middle, equalling 56% of L. RV (Figure 5B) being equally long, and with greatest H 49% of L. Valves asymmetrical: left one clearly higher than right one, overlapping it with flange dorsally. RV overlaps left one posteroventrally. Right valve with more straight caudal margin than in LV. Marginal zone frontally 23% of L, while caudally 13%. Greatest W (Figure 1B) equals 33% of L. Other features of carapace same as in male.

A2 4-segmented (Figure 6A). Aesthetasc Y equals 55% of first endopodal segment; y1 not reaching distal end of penultimate segment, y2 two times as long as terminal segment, while y3 5.3 times as long as same segment. All "t" setae on posterior side of second endopodal segment developed; while on anterior side of same segment one seta situated medially and slightly exceeding distal end of terminal segment. Seta z1 more claw like, while z2 and z3 setae like. Claw G2 3.8 times as long as terminal segment, G1 and G3 1.2 times as long as first endopodal segment. Claw GM as long as first endopodal segment, while Gm five times longer than terminal segment. All claws serrated. L ratio of three endopodal segments 7.3 : 4 : 1.

Endopodite of T1 (Figure 6C) with L ratio of three terminal setae 3.5 : 2.4 : 1.

T2 (Figure 6B) with smooth claw.

Fu (Figure 5D) with claws almost equally long, and 0.8 times as long as anterior furcal margin. Genital lobe rounded, and without any appendages. All other morphological features same as in male.

Variability

Valve L of females range from 0.600 mm to 0.635 mm (average 0.619 mm; n=7), while in males they range from 0.670 mm to 0.673 mm (average 0.671 mm; n=3). No other forms of variability was observed.

Etymology

The species name comes from the Latin noun "admiratio" (f.), meaning wonder.

Female (WAM C28405) - Western Australia, Yilgarn Craton, Upper Brockman, unused water bore on river terrace, 22 August 1999, leg. W. F. Humphreys, 31°21'S 116°07'E (BES: 7668): dissected on one slide.

Paratypes

Western Australia, Yilgarn Craton, Upper Brockman, unused water bore on river terrace, 22 August 1999, leg. W. F. Humphreys, 31°21'S 116°07'E (BES: 7668): two females [one on slide (WAM C28406), other in alcohol (WAM C28407)].

Description

Male (holotype). L of LV 0.648 mm, greatest H situated around middle and equalling 54% of L. RV being smaller and 0.629 mm long, with greatest H as well around middle and equalling 50% of L. Carapace in lateral view (Figure 7A) subtriangular. Doral margin arched, slopping evenly towards frontal margin and more inclined towards caudal one. Caudal margin almost straight, while frontal one widely rounded. Ventral margin slightly concave around mouth region, than slightly convex frontally. RV overlaps right one with clear flange dorsally. Marginal zone wider anteriorly (17% of L) than posteriorly (7% of L). Marginal pore canals not observed. Selvage peripheral frontally, not visible caudally. Carapace in dorsal view (Figure 7B) frontally cuneiform and narrower than caudally. LV overlaps right one on both ends. Greatest W around middle equalling 33% of L. Surface of carapace smooth and hairy.

A1 7-segmented (Figure 9A). First segment with
two setae anteriorly (proximal reaching distal margin of second segment, distal reaching only middle of same segment), and two setae posteriorly (almost reaching distal end of fifth segment). Second segment with one seta anteriorly reaching distal end of fourth segment. Third segment without any seta. Fourth segment with two long setae anteriorly, and one shorter posteriorly (reaching middle of following segment). Fifth segment with two long setae anteriorly, and one shorter posteriorly (reaching middle of terminal segment). Penultimate segment with two long setae, and short one (hardly reaching distal end of terminal segment) anteriorly, while same segment more posteriorly carries one seta that exceeds distal end of terminal segment. Seventh segment with two long and one short seta (about two times longer than segment), and aesthetasc (ya) 5.4 times longer than terminal segment. All five terminal segments of about same L.

A2 5-segmented (Figure 9C). Exopodite plate with one long seta and two short ones. Aesthetasc Y equals 62% of first endopodal segment; y1 slightly exceeds distal end of third segment; y2 about two times as long as terminal segment; y3 six times as
long as same segment. First endopodal segment postero-distally with two unequal setae: one reaching middle of terminal claws, other distal end of penultimate segment. Male's bristles present. Penultimate segment with three long claws, subequally long (1.4 times as long as first endopodal segment), that represent claw G2 and two transformed z setae (z1 and z2). Penultimate segment also with two smaller claws – G1 (4.5 times as long as terminal segment), and G3 (four times as long as terminal segment), as well as with one short – z3 seta (two times as long as terminal segment). Terminal segment with two claws: GM (1.1 times as long as first endopodal segment), and Gm (three times longer than terminal segment). L ratios of four endopodal segments 7.7 : 2.4 : 2 : 1

Md (Figure 9D). Coxa with about seven terminal teeth. Palp four-segmented. First segment with two long setae (pappose – S1), and two short (pappose – S2). Second segment with two setae externally (reaching middle of following segment), internally with 3+2 setae in bunch. Penultimate segment with three setae externally, and four intero-distally. Gamma seta smooth. Terminal segment with fused claw, distally pappose. On external side of claw one strong seta, internally two thin setae present. L : W

of terminal segment 1.25 : 1. L ratios of three distal segments 1 : 4.6 : 1.

Mxl palp (Figure 7D) with penultimate segment distally with four pappose setae. Terminal segment rectangular with two claws and four setae.

T1 asymmetrical: right one (Figure 8D) more robust than left one (Figure 8C). On both palps main body robust, fingers stocky. Subterminal sclerotized structures thin and elongated on right palp, while button-like on left one. Exopodite consists of two unequal setae. Protopodite with one “Ta” seta. Setae “Tb” and “Td” also present.

T2 (Figure 8A) five-segmented. Basal segment with one pappose seta. First and second endopodal segments with one seta each, penultimate segment with two setae. Terminal segment with two setae and claw which distally strongly serrated and 1.3 times as long as three distal segments combined.

T3 (Figure 8B) 5-segmented. Basal segment with only two setae (d1 and dp). First and second endopodal segments without any seta, penultimate with one distal seta which reaches distal end of terminal segment. Terminal segment with three unequally long setae, smallest one being two times
A new genus of Candoninae

Figure 10  *Acandona memoria* gen. nov., sp. nov. A, B holotype male (L 0.648 mm); C–F allotype female (L 0.619 mm): A – Fu; B – furcal attachment; C – Fu with genital lobe; D – furcal attachment; E – protopodite of T1; F – T2, detail. Scale = 0.1 mm.

as long as terminal segment. L ratios of three setae as follows 3.5 : 2.2 : 1.

Fu (Figure 10A) with both furcal claws and setae developed. Anterior and posterior claws almost equally long and finely serrated. Posterior seta situated very low on furcal trunk. Claws 0.9 times as long as anterior furcal margin. Furcal attachment shown on Figure 4B.

Hemipenis (Figure 7C) robust, with lobe “a1” triangular, a2 rounded, while lobe “h” rounded. Lobe “b” with inclined distal margin.

Zenker’s organ with seven rows of spines.

Female (allotype). L of LV 0.619 mm, with greatest H around middle, equalling 53% of L. RV 0.615 mm, and with greatest H 48% of L. Valves asymmetrical: left one clearly bigger than right one, overlapping it with flange dorsally (Figure 11A). Caudal margin less straight than in males, frontal more protrude than in male. Marginal zone frontally 22% of L, while caudally 16%. Greatest W (Figure 11B) equals 31% of L. Other features of carapace same as in male.

A2 4-segmented. Aesthetasc Y equals 55% of first endopodal segment (Figure 11C); y1 not
reaching distal end of penultimate segment, \( y_2 \) 1.8 times as long as terminal segment, while \( y_3 \) 4 times as long as same segment. All “t” setae on posterior side of second endopodal segment developed; while on anterior side of same segment one seta situated medially and almost reaching distal end of terminal segment. Seta \( z_1 \) more claw like, while \( z_2 \) and \( z_3 \) setae like. All \( z \) setae about two times as long as terminal segment. Claw \( G_2 \) as long as first endopodal segment, \( G_1 \) and \( G_3 \) 1.4 times as long as same segment. Claw \( G_{M} \) 1.25 times as long as first endopodal segment, while \( G_m \) slightly longer than same segment. All claws serrated. \( L \) ratio of three endopodal segments 5 : 2.7 : 1.

Endopodite of \( T_1 \) (Figure 10E) with three subequally long distal setae.

\( T_2 \) (Figure 10F) with claw less serrated than in male.

\( T_3 \) (Figure 11E) with three setae on basal segment.

\( F_u \) (Figure 10C) with anterior seta slightly longer than in male. Claws almost equally long, and 0.9 times as long as anterior furcal margin. Genital lobe rounded, and without any appendages.

All other morphological features same as in male.
The presence of two "a" lobes is found in the genus Caribecandona Broodbakker, 1983. This genus, on the other hand, has six-segmented A1, reduced posterior furcal claw and absent posterior furcal seta. The general appearance of the hemipenis, especially the manner in which lobe "a1" is extended, is similar to that in the genera Candona Baird, 1835 and Eucandona Daday, 1900, where, in contrast to Acandona, the "M" process is well sclerotized, and the furcal trunk is longer in the relation to the anterior furcal claw. A flat, weakly sclerotized "M" process in Acandona is also characteristic of the genus Pseudocandona Kaufmann, 1900 but in this genus no species has two "a" lobes. It would be hard to distinguish Pseudocandona from the new genus by the chaetotaxy of the third thoracic limb because the two new species have different chaetotaxy of this leg, but also due to the variable number of setae on the basal segment in A. memoria. All Pseudocandona species lack "Tf" seta. There is a variable number of setae on the basal segment in Pseudocandona albicans (Brady, 1864), as Martens (1982) reported specimens of this species having two setae on the basal segment of the third thoracic limb. Similar variability has not been recorded for any other species of Pseudocandona. The systematics of the genus Pseudocandona is probably the most difficult as this genus has many species that reproduce exclusively parthenogenetically, so the appearance of the hemipenis, which is the only clear morphological character discriminating a large number of species, remains unknown. This genus is divided into six species groups (see Karanovic, 1999b), but is still in need of revision to resolve taxonomic problems. Despite variability in the chaetotaxy of the cleaning leg, Meisch's (1996) revision of the subfamily, based on this chaetotaxy, is shown to be useful to discriminate the many Holarctic genera in which this character remains constant.

No other genus of Candoninae can be confused with Acandona, as it has completely developed furca whereas this exhibits various levels of reduction (without posterior furcal seta, reduced or absent posterior furcal claw) in Namibcypris Martens, 1992, Danielocandona Broodbakker, 1983, Meischcandona Karanovic, 2001, Indocandona Gupta, 1984, Caribecandona Broodbakker, 1983, Cubacandona Broodbakker, 1983, Candonopsis Vavra, 1891 and Phreatocandona Danielopol, 1978. In Terrestricandona Danielopol & Betsch, 1980, the terminal segment of the third limb has one sclerotized seta; Namnocandona Ekman, 1914 has a five-segmented A1 (seven-segmented in Acanodna); in the genera Trajancandona Karanovic, 1999 Schellencandona Meisch, 1996 and Baicalocandona Mazepova, 1976, Zenker's organ consists of six rows of spines (seven rows in Acanodna). The three new genera of
Candoninae recently described from Australian subterranean waters (Karanovic & Marmonier, in press) show greater similarity with the subtropical and tropical Candoninae and they are clearly different from Acandona which is more closely related to the Holarctic genera.

ACKNOWLEDGEMENTS

This paper is a part of the project financed from the Australian Biological Resources Study (ABRS) Grant, given to the author for the years 2002 and 2003. I would like to thank Dr William F. Humphreys (Western Australian Museum) for the Australian Biological Resources Study (ABRS) related to the Holarctic genera.
