email: morgan@possum.murdoch.edu.au

INTRODUCTION
Considering the enormous number of fish imported into Western Australia each year by the aquarium trade (ca 600 000 individual fish/year from overseas destinations – this figure does not include fish imported from elsewhere in Australia) (W. Cross, personal communication – Australian Quarantine and Inspection Service), it is fortunate that very few species have established wild populations here. Although only a small number of introduced aquarium species, such as tilapia *Oreochromis mossambicus* (Cichlidae), goldfish *Carassius auratus* (Cyprinidae), carp *Cyprinus carpio* (Cyprinidae), one-spot livebearers *Phalloceros caudimaculatus* (Poeciliidae) and the mosquitofish *Gambusia holbrooki* (Poeciliidae), are presently entrenched in Western Australian inland waters (Trendall and Johnson, 1981; Allen, 1989; Pen and Potter, 1991; Morgan et al., 1998; Kailola et al., 1999; WA Museum Records; unpublished data), the sheer numbers of these and other species entering the state guarantee an uncertain future. The species mentioned above have either been deliberately or accidentally released into various waterbodies throughout the state and, as this paper highlights, it is probably only a matter of time before other non-native species establish self-maintaining populations in Western Australia.

Many introduced species not only compete with native fish for food and habitat, but may also exhibit agonistic behaviour towards or prey on native fish, often displacing them from their preferred habitat or even replacing them in entire systems (e.g. Arthington and Lloyd, 1989; Hutchinson, 1991; Gill et al., 1999; Kailola et al., 1999). Although Western Australia has some of the strictest quarantine laws in the country with regard to most imports, incoming aquarium fish, particularly those entering via eastern Australia, are subjected to only limited checks, thereby increasing the risk of introducing noxious species and/or diseases or parasites that may be harboured either in or on the fish or in the water in which they are transported.

While the green swordtail *Xiphophorus helleri* (Poeciliidae) (Figure 1) has long been imported into Australia for use in the aquarium trade, a self-maintaining population has not previously been captured in the natural waterways of Western Australia. Feral populations of this species have, however, been found in some drainages in Queensland since the 1960's as well as in New South Wales, the Northern Territory and also in the drainages of Lake Eyre (McKay, 1978; Thompson, 1982; Milton and Arthington, 1983; Arthington and Lloyd, 1989; Kailola et al., 1999). *Xiphophorus helleri*, which originates from eastern drainages of central America (Mexico southward to northern Honduras) (Miller, 1966), is a livebearing species that exhibits sexual dimorphism, i.e. the males develop a long 'sword' from the lower rays of their caudal fin and their anal fin becomes modified to form a gonopodium (intromittent organ for internal fertilisation) (Constantz, 1984). Captive bred fish exhibit a variety of colours but are generally an overall bright orange, fish from wild populations on the other hand, are olive brown to green with a narrow lateral stripe, the male retaining the orange coloration in the sword of the caudal fin (Figure 1).

While it is has been demonstrated that *G. holbrooki* is impacting on, and causing a decline in, the native freshwater fish fauna of both south-western and eastern Australia through both competition for limited food resources and habitat and aggressive behaviour (e.g. McKay, 1978; Arthington et al., 1983; Hambleton et al., 1996; Gill et al., 1999), the effects of other poeciliids on the native fish fauna has attracted only limited research. It is known, however, that male X. helleri form long term hierarchies and are to an extent territorial, spending much of their time aggressively fighting with other males and possibly other species (Franck and Ribowski, 1993).

This paper reports the first finding of a self-maintaining population of X. helleri in south-western Australia and aims to increase the public awareness of the impacts associated with the release of non-native species into Western Australia. It also
highlights the need for more stringent regulations regarding the importation of exotic species for the aquarium industry.

**MATERIALS AND METHODS**

As part of a fish survey of the inland waters between Perth and Murchison, a total of eight sites along a 60 km stretch of the Irwin River and its tributaries (near Dongara ca 360 km north of Perth) were sampled for fish during summer 1998/99 (Figure 2). Fish were captured using seine nets comprised of 3 mm woven mesh. Fish were identified, with those species native to southwestern Australia immediately returned to the water, while all individuals of the introduced green swordtail *Xiphophorus helleri* were anaesthetised in benzocaine and placed into 100% ethanol. The total length (TL), which excludes the sword, of each fish was measured to the nearest mm.

**RESULTS AND DISCUSSION**

*Xiphophorus helleri* was found to occur at five of the six sites (i.e. sites 2-5 and 7) sampled along a 42 km stretch of the Irwin River between the town bridge (site 2) and Strawberry Bridge (site 7) (salinity range 0.3 – 2.4 ppt) (Figure 2). No *X. helleri* was captured at the site sampled downstream of town bridge (i.e. site 1) which was at the mouth of the river (salinity = 13.7 ppt) or at the only site that contained water upstream of Strawberry Bridge (i.e. Depot Hill Rd – site 8) which was almost dry. No fish was captured at the site sampled on Sand Plain Creek (i.e. site 6), which had previously dried. The mean densities of *X. helleri* at sites 2–5 and 7 ranged from 0.05 to 5 fish m⁻², while the lengths of fish at these sites ranged from 13 to 56 mm TL, respectively. The presence of large numbers of very small juveniles, and the fact that many of the males had recently spawned and that some of the females were pregnant, demonstrates that the Irwin River population is self maintaining. Co-occurring species, at the sites downstream of the weir at Mountain Bridge (site 4), included black bream (*Acanthopagrus butcheri*), Swan River gobies (*Pseudogobius olorum*) and sea mullet (*Mugil cephalus*). Although there are no data or museum records available on the distribution of fish in the Irwin River, it is possible that the endemic freshwater teleosts, the western pygmy perch *Edelia vittata* and the western minnow *Galaxias occidentalis*, were once (and still may be) in the catchment. Both of these species have been found by the first author in the Arrowsmith River which is only 10 km to the south of Sand Plain Creek, a tributary of the Irwin River.

Information regarding the impacts of *X. helleri* on the native fauna is unavailable, however, Arthington (1989) found this species in waters around Brisbane to be omnivorous, consuming algae, plant matter, aquatic invertebrates (e.g. chironomids, oligochaetes, coleopterans, trichopterans, hemipterans, molluscs and other fish) and also terrestrial invertebrates (e.g. insects and arachnids). They found that the majority of guts examined contained, on average, large amounts (ca 88% by volume) of amorphic, partly digested material which included plant fragments, filamentous algae and diatoms. Since the reproductive cycle of female *X. helleri* apparently ceases only when water temperatures fall below
Xiphophorus helleri in south-western Australia

Figure 2 The sites sampled for green swordtails Xiphophorus helleri in the Irwin River, Western Australia.

15°C (Milton and Arthington 1983), this species is capable of reproducing for an extensive period throughout most of Western Australia, with only winter/spring in the south-west recording temperatures less than 15°C. In the Brisbane region (a latitude similar to that of the Irwin River), over 30% of females were pregnant in every month of the year except June (Milton and Arthington, 1983), with new recruits also appearing in these months. Furthermore, individuals of this species can mature at a small size (ca 23 and 27 mm for females and males, respectively), have a higher mean fecundity than the extremely successful G. holbrooki (ca 60 versus ca 23), have a short gestation period (between 24 and 63 days) and thus have the potential to produce up to 12 broods per year (Milton and Arthington, 1983; Kailola et al., 1999). This species can also tolerate a wide range of temperatures and salinities and is able to survive in oxygen deficient waters by gulping at the air-water interface (Arthington et al., 1986). Green swordtails, which may reach over 100 mm TL, have even been shown to out compete and dominate the aggressive and very successful G. holbrooki (Arthington et al., 1986). Thus, while X. helleri is only currently found in the Irwin River in Western Australia, the fact that it can utilise an array of food/prey types, produces live young, can generate very large populations in a short period, lacks environmental constraints and is able to coexist with and even outcompete G. holbrooki (Milton and Arthington, 1983) makes the swordtail a species that should be declared a pest.

While it may not be possible to eradicate this species from the Irwin River, it may be possible to limit future introductions through both public education and the removal of this species from aquarium shops. The fact that many aquarium species are relatively hardy, easy to maintain and reproduce readily makes them a potential threat to the unique fauna of Western Australia should they escape or be released into the wild. It should be the responsibility of the Fisheries Department of
Western Australia to identify and then prohibit species which, if released into the wild, are capable of readily establishing feral populations. Future surveys of the south-west, particularly within populated areas, will undoubtedly reveal other non-native species that have established populations as a result of deliberate releases.

ACKNOWLEDGEMENTS

Thanks are extended to the Natural Heritage Trust, Fisheries WA, Water and Rivers Commission of WA and Murdoch University for funding the survey of the waters between Perth and Murchison. Thank you very much to Charlotte Morgan for help with the field work.

Guide to Authors

Subject Matter:
Reviews, observations and results of research into all branches of natural science and human studies will be considered for publication. However, emphasis is placed on studies pertaining to Western Australia. Longer papers will be considered for publication as a Supplement to the *Records of the Western Australian Museum*. Short communications should not normally exceed three typed pages and this category of paper is intended to accommodate observations, results or new records of significance, that otherwise might not get into the literature, or for which there is a particular urgency for publication. All material must be original and not have been published elsewhere.

Presentation:
Authors are advised to follow the layout and style in the most recent issue of the *Records of the Western Australian Museum* including headings, tables, illustrations and references.

The title should be concise, informative and contain key words necessary for retrieval by modern searching techniques. An abridged title (not exceeding 50 letter spaces) should be included for use as a running head.

An abstract must be given in full length papers but not short communications, summarizing the scope of the work and principal findings. It should normally not exceed 2% of the paper and should be suitable for reprinting in reference periodicals.

The International System of units should be used. Numbers should be spelled out from one to nine in descriptive text; figures used for 10 or more. For associated groups, figures should be used consistently, e.g. 5 to 10, not five to 10.

Spelling should follow the *Concise Oxford Dictionary*.

Systematic papers must conform with the International Codes of Botanical and Zoological Nomenclature and, as far as possible, with their recommendations.

Synonymies should be given in the short form (taxon, author, date, page) and the full reference cited at the end of the paper. All citations, including those associated with scientific names, must be included in the references.

Manuscripts:
The original and two copies of manuscripts and figures should be submitted to the Editors, c/-Publications Department, Western Australian Museum, Francis Street, Perth, Western Australia 6000. They must be in double-spaced typescript on A4 sheets. All margins should be at least 30 mm wide. Tables plus heading and legends to illustrations should be typed on separate pages. The desired position for insertion of tables and illustrations in the text should be indicated in pencil. Tables should be numbered consecutively, have headings which make them understandable without reference to the text, and be referred to in the text.

High quality illustrations are required to size (16.8 cm x 25.2 cm) or no larger than 32 cm x 40 cm with sans serif lettering suitable for reduction to size. Photographs must be good quality black and white prints, not exceeding 16.8 cm x 25.2 cm. Scale must be indicated on illustrations. All maps, line drawings, photographs and graphs, should be numbered in sequence and referred to as Figure/s in the text and captions. Each must have a brief, fully explanatory caption. On acceptance a computer disk containing all corrections should be sent with amended manuscript. The disk should be marked with program (e.g. Word, WordPerfect, etc).

In papers dealing with historical subjects references may be cited as footnotes. In all other papers references must be cited in the text by author and date and all must be listed alphabetically at the end of the paper. The names of journals are to be given in full.

Processing:
Papers and short communications are reviewed by at least two referees and acceptance or rejection is then decided by the editors.

The senior author is sent one set of page proofs which must be returned promptly.

The senior author will receive fifty free offprints of the paper. Additional offprints can be ordered at page proof stage.
