

MOLLUSCS OF CHRISTMAS ISLAND

Fred E. Wells and Shirley M. Slack-Smith

Western Australian Museum, Francis Street, Perth, Western Australia 6000, Australia

Christmas Island is towards the lower end of species diversity for similar coral reef surveys undertaken by the Western Australian Museum (Table 8), with a total of 313 species of molluscs collected (Table 9). Mollusc diversity was greater at Christmas Island than the 261 species collected at Rowley Shoals and the 279 collected at Scott Reef in 1984, but fewer than the 433 collected at Ashmore Reef in 1986. However, with 15 collecting days compared to the maximum of 12 on Ashmore Reef and the fact that there were three people primarily interested in molluscs on Christmas Island as opposed to two on the other expeditions, the molluscan fauna of Christmas Island can be seen to be restricted.

A similarly restricted molluscan fauna was reported for the Chagos Islands (384 species; Sheppard, 1984) and the Cocos (Keeling) Islands (Wells, 1994). A total of 380 species was collected during the Western Australian Museum expedition to Cocos (Keeling). Maes (1967) had extensively surveyed intertidal regions of Cocos (Keeling). Despite the presence of a much more extensive littoral and shallow sublittoral area and a much more diverse range of habitats than at Christmas Island, a list of only 610 species known from Cocos (Keeling) was compiled from a number of collecting

sources. Maes considered that the paucity of species was largely due to the great distances over which planktonic larvae would have to be carried from areas of similar habitats, further complicated by apparently adverse winds and currents.

Of the 313 species collected at Christmas Island, 245 were gastropods (78.3%) and 63 were bivalves (20.1%). No scaphopods, only three species of chitons and two of cephalopods were collected although other cephalopod species were seen. This breakdown of the fauna is almost identical to the results from the northwestern shelf-edge atolls of Western Australia, where 77.3% of the total of 581 species collected were gastropods and 20.7% were bivalves (Wells, 1994). The number of bivalve species in these offshore habitats is undoubtedly low at least partly because of the restricted amount of sandy and muddy habitats in which they are diverse. Sandy subtidal areas were found in a few restricted areas of Christmas Island, particularly at Flying Fish Cove. In contrast to the bivalves, terebrids were diverse in the sand, with 13 species collected.

Flying Fish Cove has the greatest range of habitats encountered on Christmas Island, and the molluscs were accordingly diverse, with a total of 212 species collected. This represents 68% of all molluscs species collected.

Table 8 Numbers of mollusc species collected during surveys of the faunas of coral reefs on the north coast of Western Australia and adjacent parts of the Indo-Pacific Ocean.

There are several other published reports on the marine molluscs of Christmas Island which list additional species not found by the Western Australian Museum survey. The most extensive of these is a book on the marine molluscs of the island (Wells *et. al.*, 1990) which illustrates a total of 380 species, 110 of which were not collected by the Western Australian Museum trip. Other reports are by Smith (1887, 1900, 1911), Iredale (1917), Tomlin (1934), Laidlaw (1935), Laseron (1958), and Colman (1985). If these reports are considered the total known marine molluscan fauna of Christmas Island is approximately 510 species (Table 9).

A characteristic of the molluscan fauna observed in 1987 was that only juveniles represented many species. That this was not just a seasonal phenomenon is indicated by the inclusion in this group of long lived molluscs such as *Tridacna* spp., *Terebra maculata*, *Pteria penguin* and *Isognomon* spp.

ACKNOWLEDGEMENTS

We are pleased to acknowledge the help of Mr Clay Bryce in all aspects of the fieldwork and Mrs G.M. Hansen in identifying many of the mollusc species collected.
