**ABSTRACT** – Barrow Island is Western Australia's second largest offshore island and its flora and fauna have been able to evolve without major human disturbances. Chevron Australia Pty Ltd and its Joint Venture Participants made an application to construct a plant to liquefy natural gas on the island in 2001. One of the conditions under which approval was granted was the implementation of a rigorous biosecurity effort to ensure that no non-indigenous species (NIS) are introduced or allowed to establish on the island. To fulfil this condition it was first necessary to characterise what was already present on the island. A series of surveys have been performed using a purpose-designed sampling protocol in order to provide baseline data on the existing terrestrial invertebrates on Barrow Island. A total of 1,873 morphospecies were sampled but subsequent surveys and taxonomic developments have increased the count to 2,397. This compares with an estimated species richness of 2,481 terrestrial invertebrate species on the island. Composition of the fauna varied considerably between the wet and dry seasons and between years, even when samples were taken during the same month. Composition also varied with distance from the coast, which may be associated with soil type and vegetation association. Twenty five non-indigenous species and seven putative non-indigenous species have been found, all of which are believed to have been present prior to commencement of the Gorgon Gas Development project.

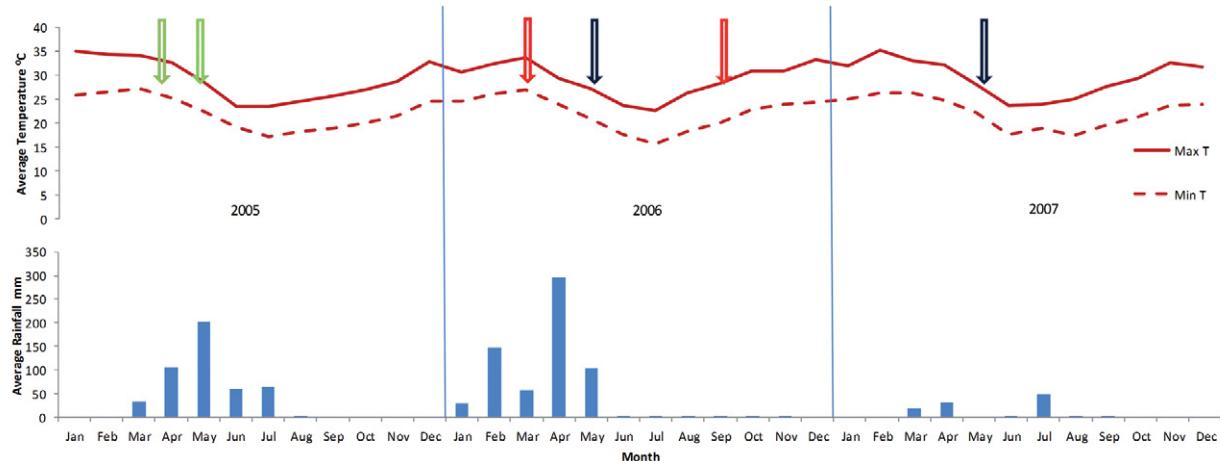

**KEYWORDS:** species inventory, biodiversity survey, non-indigenous species, offshore island.

## INTRODUCTION

Barrow Island is Western Australia's second largest offshore island. Separated from the mainland for 8,000 years, uninhabited by indigenous people and un-colonised by Europeans, Barrow Island's flora and fauna have been able to evolve without major human disturbances. Discovery of large gas deposits in the north-west shelf prompted Chevron Australia Pty Ltd and its Joint Venture Participants (see acknowledgements) to make an application to construct a plant to liquefy natural gas on the island in 2001. A number of conditions accompanied final approval of the Gorgon Project. Included amongst these was the need to implement a rigorous biosecurity effort to ensure that no non-indigenous species (NIS) are introduced or allowed to establish on the island. Furthermore, the conditions required the design and implementation of a detection program with a detection power of 0.8, or an appropriate alternative power, for detecting NIS at an early enough stage that eradication could be attempted without

causing undesirable environmental consequences (Government of Western Australia 2007). In other words, if a non-indigenous species was to arrive on the island, there should be at least an 80% certainty that it would be detected.

Although this was a straightforward undertaking for plants and vertebrate animals because these components of the biota are well known on Barrow Island (Chevron Texaco Pty Ltd. 2005; Moro and Macauley 2010a, b and c), lack of data made this a problematic task for the invertebrates. There had been a few taxon-specific surveys performed in the 1970s through to the 1990s (Solem 1997—land snails; Perry 1972—termites; Smithers and Butler 1985—dragonflies; Smithers 1984a—psocopterans; Smithers and Butler 1983—butterflies; Smithers 1984 b, 1988—neuropterans) but most of these were not exhaustive, having been carried out during short, single visits to the island. Recognising this deficiency, Chevron contracted entomologists at Curtin University to carry out a baseline survey of the terrestrial invertebrate fauna of Barrow Island (BWI).

**FIGURE 1** Monthly total rainfall and mean monthly minimum and maximum temperatures for the period covering the Pilot Study (green arrows), the Gas Plant survey (red arrows) and the Non-Indigenous Species surveys (black arrows).

Prior to commencing the survey, it was necessary to design a sampling protocol that was cost-effective, while still being adequate to sample the species present. A transect-based approach formed the basis of the protocol, and built upon a design that had been used for many years in rehabilitated mine sites for sampling invertebrates from all strata; ranging from the litter layer up to the trees (shrubs in the case of Barrow Island) (Allen 1989). Once the sampling protocol had been agreed upon, two separate, but complementary surveys were performed. The Gas Plant (GP) survey targeted the area where the gas processing plant was to be built and was designed to sample the species most likely to be affected by the development. This positioning of the transects was designed to enable us to elucidate the major determinants of the composition of the invertebrate fauna, including soil type, vegetation association, distance from the coast, and season. Paired transects were set up both close to and distant from the proposed gas plant in order to provide a basis for ecological monitoring of potential edge effects. The second survey was designed to detect whether any non-indigenous species (NIS) already exist on the island and targeted areas of current or previous disturbance – areas where NIS are most likely to be found.

The results of the two surveys have been comprehensively reported on by Callan et al. (2011). The results are summarised here and findings have been updated in the light of further taxonomic information being provided. This formed the

baseline species list of indigenous and non-indigenous species inhabiting Barrow Island which was subsequently used in conjunction with the potential NIS threats to the island to develop the surveillance program, described in the papers by Whittle et al. (2013 a, b).

## PILOT STUDY

The pilot study was performed twice, once during the week beginning 22 April 2005 and once during the week of 1 May 2005, immediately after a significant rain event (Figure 1). Seven native vegetation sites and three disturbed sites (airport, old rubbish dump and accommodation camp) were sampled. Sampling was based upon a 90 m transect and included pitfall trapping, herb and shrub vacuum sampling (10 swathes at 90° to the transect), shrub beating (10 small trees or shrubs close to each pitfall trap), litter sampling using Winkler sacks (Agosti et al. 2000) and hand collecting for one hour during both daytime and night. Pitfall trap configurations included small (43 mm internal diameter) versus large (110 mm) traps, 10 versus 20 small diameter traps, and 5 versus 10 days of small diameter trapping.

The resulting material was sorted to morphospecies and individual groups were sent to the relevant taxonomists for determination, resulting in a list of approximately 550 morphospecies. Then, for selected groups, the number of species per sampling technique was summed, the estimated total number of species

was calculated from species accumulation curves, the efficacy of each method was compared, and the complementarity between the different methods was assessed. From this, a standardised sampling protocol was agreed upon, and is summarised in Figure 2.

The finalized protocol was once again based on a 90 m transect, with 10 small-diameter pitfall traps with ethylene glycol preservative, run for 5 day periods following a 12 hour digging-in period. Leaf litter was taken from close to each pitfall trap and coarse-sieved to remove large litter fragments. The resulting material was placed in Winkler sacks and invertebrates were extracted over a 4-day period. Three vegetation vacuum swathes were taken in 30 x 15 m areas parallel with the sampling transect. To complement this, 10 small trees or shrubs were sampled by beating with a stout stick over a net.

Finally, invertebrates were hand collected from a range of microhabitats in a 100 m radius around each transect for 1 person-hour during the day and 2 person-hours during the night. Light traps were also run at a third of the GP and NIS sites, selected to maximise their spread across the island.

### GAS PLANT (GP) SURVEY

Twelve sites were sampled during this survey, representing coastal dunes, floodplain vegetation, and a range of limestone sites ranging from flats to ridges. Wherever possible, sites of comparable vegetation were in duplicate pairs, with one site proximal to the future gas plant and the other some distance away (Figure 3a). This was designed to characterise the fauna close to the areas that will be disturbed and to enable monitoring of any spill-

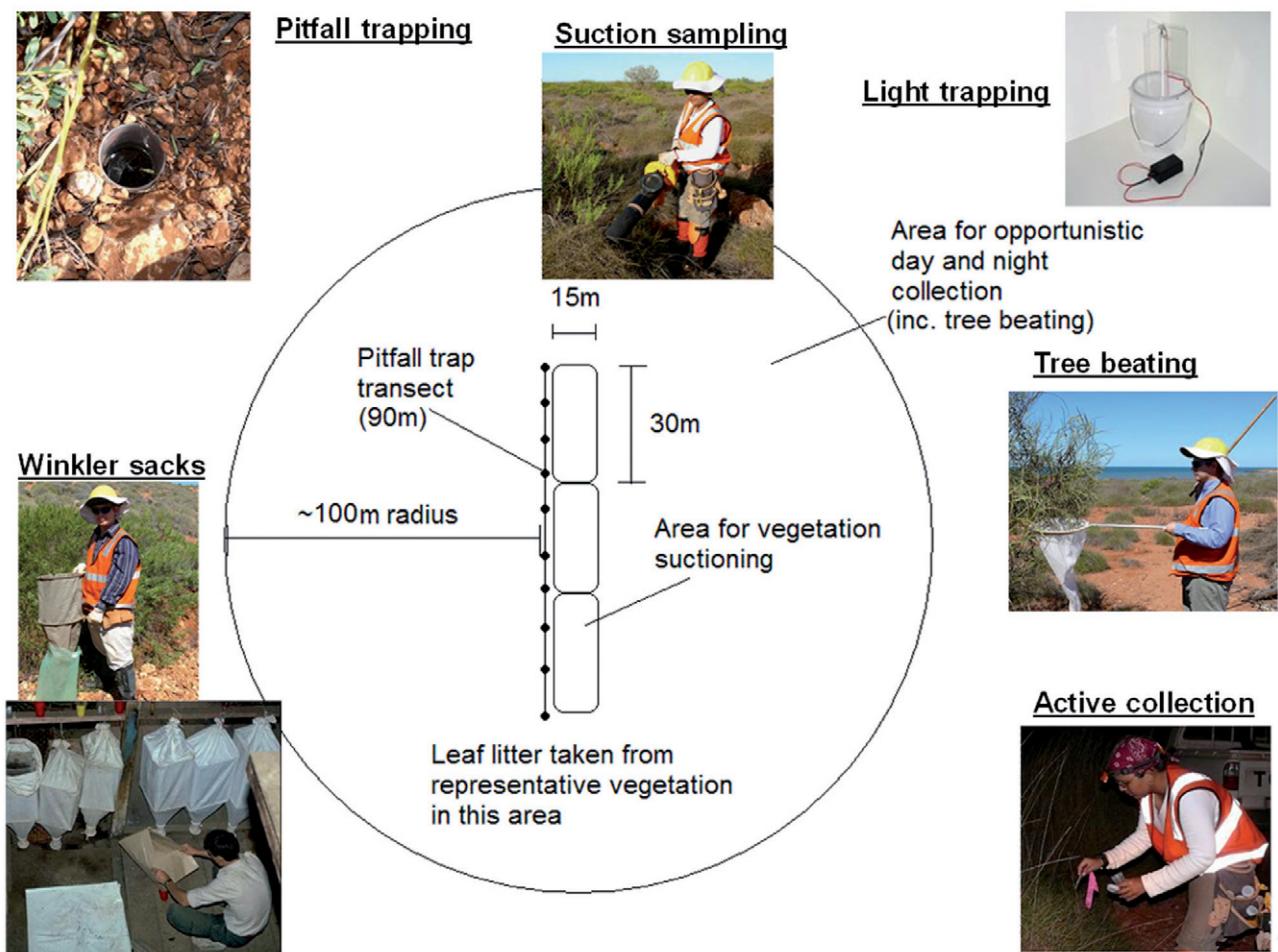

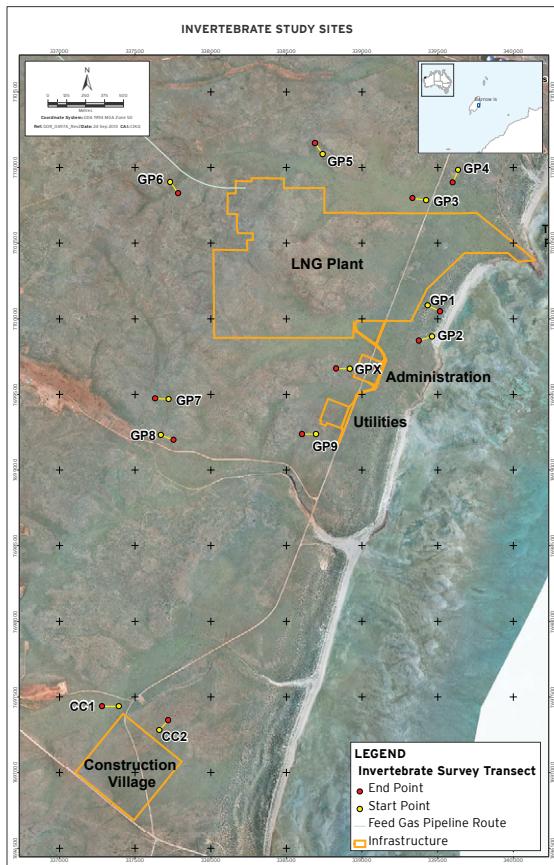

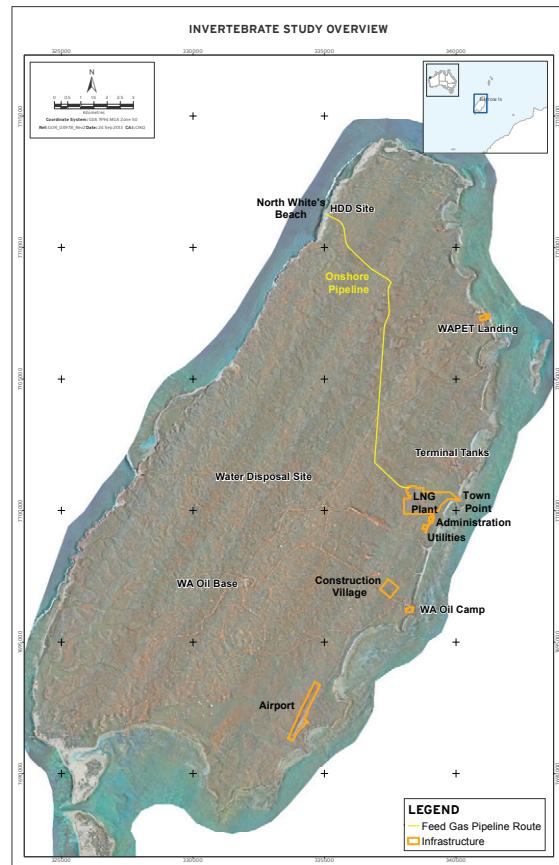

FIGURE 2

Standardised sampling protocol used for the GP and NIS surveys. Further details are explained in the text; design of the protocol was modified in some of the NIS sites to allow for irregular shape of the areas and the existence of structures of interest, such as buildings.

A

B

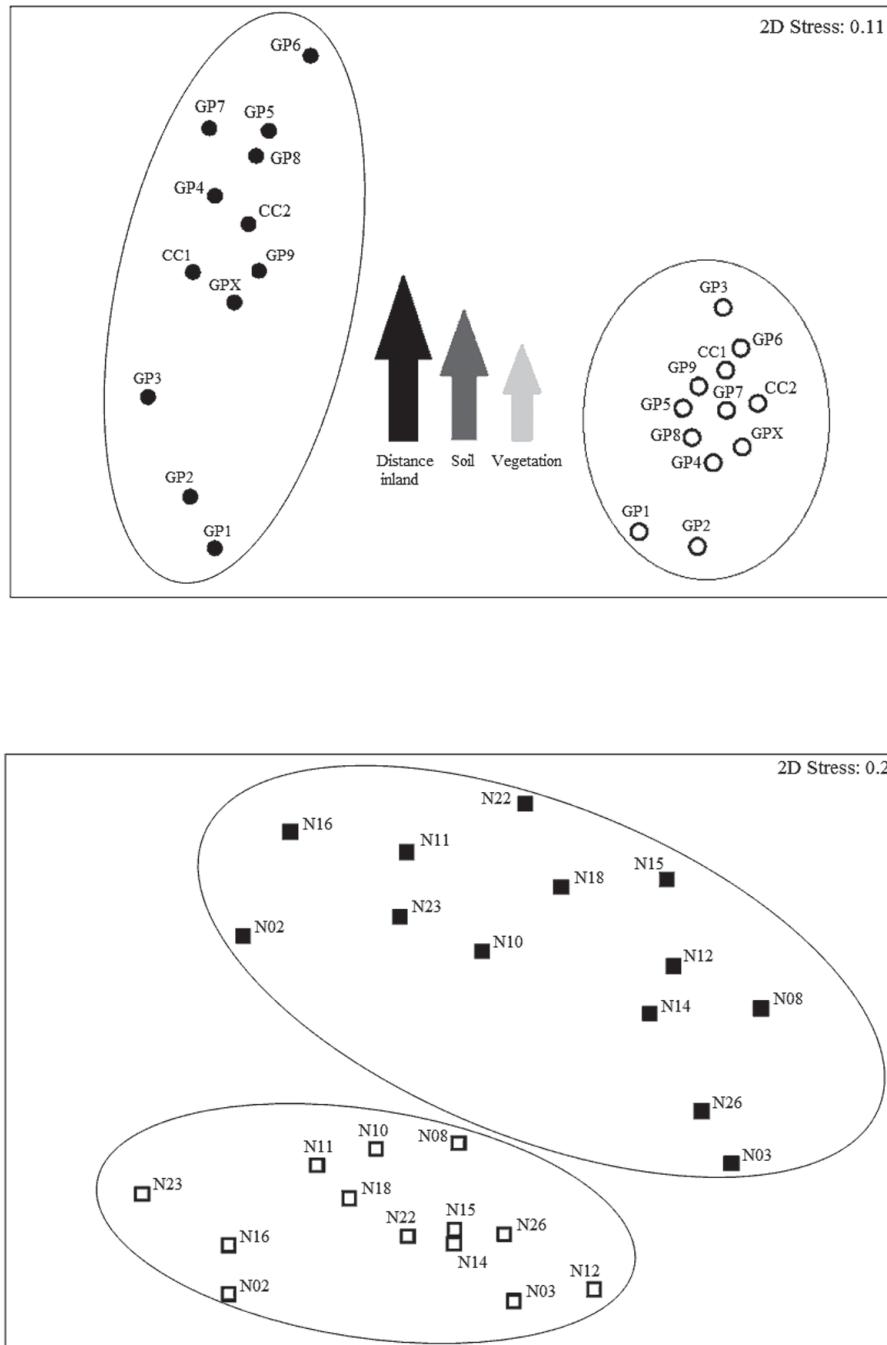

**FIGURE 3** Location of the (A) undisturbed (GP) and (B) disturbed (NIS) survey sites where invertebrates were sampled using the standardised sampling protocol. Note some of the infrastructure positions have changed since the time when these surveys were undertaken.

over impacts on the environment by comparing proximal and distant sites within each vegetation type, the identity of which can be obtained by consulting Appendix C1 of the EIS/ERMP for the Gorgon Development on Barrow Island (Chevron Texaco Pty Ltd. 2005). Sampling was performed using the protocol shown in Figure 2 and was carried out twice, once in the fortnight beginning 15 March 2006 at the end of the wet season and again in the period beginning 25 September 2006 at the end of the dry season. The pattern of rain around these times is shown in Figure 1 and recent falls prior to the first sampling period had resulted in a flush of green vegetation, which was not so evident during the second period.

A total of 1,123 morphospecies were collected during the two periods, comprising four Mollusca species, 165 Arachnida species, nine Malacostraca species, 11 Chilopoda species, two Diplopoda species, 34 Collembola species and 898 Insecta species. The full list of species encountered during the GP survey is given in Appendix 1 and the sites

by species matrices for each taxonomic group are provided in the electronic supplements to Callan et al. (2011). Vouchers of most of the species are housed in the Entomology Laboratory at Curtin University and WA Department of Agriculture and Food. They will be deposited in the Western Australian Museum upon cessation of the program.

A non-metric multi-dimensional scaling (NMDS) ordination, using Bray-Curtis matrices of non-standardised data for the most frequently occurring species in the GP survey (350 taxa), plus the environmental variables sampling time, distance from coast, soil type and vegetation type is shown in Figure 4a. The wet season and dry season samples are separated into two distinct clusters, whose species composition is significantly different (ANOSIM global  $R = 0.979$ ,  $P = 0.001$ ). Within each cluster, the relative positioning of sites along axis 2 was reasonably similar (correlation of axis 2 scores in the two seasons  $r = 0.52$ ;  $df = 10$ ,  $P = 0.05$ ) and was associated with distance from coast (ANOSIM global  $R = 0.166$ ,  $P = 0.030$ ) and weakly

**FIGURE 4**

NMDS ordination of the GP sites (top) and the NIS sites (bottom), both of which were sampled twice. The left-hand cluster of the GP ordination delimits the March 2006 wet season and the right hand cluster delimits the September 2006 dry season samples; the left- and right-hand clusters of the NIS ordination delimit the May 2006 and May 2007 samples, respectively.

**TABLE 1** List of confirmed (Status C) or putative (Status ?) non-indigenous species found during the pilot, GP, NIS and subsequent surveillance surveys carried out between 2005 and 2012. Those highlighted in bold were collected in the subsequent surveillance survey.

Order/Family	Family/Subfamily	Non-Indigenous Species of Invertebrate	Status
Araneae	Pholcidae	<i>Artema atlanta</i> (Giant daddy long legs spider)	C
Araneae	Pholcidae	<i>Crossopriza lyoni</i> (Daddy long-legs spider)	C
Araneae	Scytodidae	<i>Dictis striatipes</i> (Spitting spider)	C
Araneae	Oecobidae	<i>Oecobius navus</i> (Urban wall spider)	C

with soil type (global  $R = 0.159$ ,  $P = 0.057$ ) but not significantly so with vegetation association (global  $R = 0.078$ ,  $P = 0.174$ ). Although these variables are inevitably correlated, this indicates the importance of distance from coast and the progressively diminishing role of soil type and vegetation as determinants of faunal composition.

### NON-INDIGENOUS SPECIES SURVEY

Twenty five disturbed sites were sampled during this component of the survey. Sites were either actively used (e.g., accommodation camp, barge landing, airport, warehouse, etc.), disused (e.g., former workshop and administration areas) or restored (e.g., former waste disposal areas or sites of old accommodation camps). All sites were chosen because if any invertebrates had been previously introduced, they are more likely to be found in these areas of previous or current human activity. The NIS sites were more widely distributed across the island (Figure 3b) than the GP survey sites but the same sampling protocol (Figure 2) was adopted, although sometimes modified to suit site conditions. Sampling was performed in the week beginning 6 May 2006 and was repeated in the week beginning 1 May 2007. These periods were originally chosen as being the optimal period for sampling, as it follows on from the summer rain period. However, although this was the case during 2006, hardly any rain fell during the entire period of 2007 (Figure 1).

A total of 1,468 morphospecies were sampled in the 25 sites, represented by eight Mollusca species, 240 Arachnida species, 12 Malacostraca species, 13 Chilopoda species, three Diplopoda species, 31 Collembola species and 1,161 Insecta species. The full list of species encountered during the NIS survey is given in Appendix 1 and the sites by species matrices for each taxonomic group are provided in the electronic supplements to Callan et al. (2011).

The NMDS ordination of the 13 NIS sites that were sampled in both 2006 and 2007 and using the 316 most frequently occurring taxa are shown in Figure 4b. The two sampling periods separate out into two clearly demarcated clusters which are significantly different (global  $R = 0.687$ ,  $P = 0.001$ ), indicating the high degree of variation in fauna between years, probably due to differences in the pattern and amount of rainfall. Although environmental variables were included in the analysis, no influences on the fauna of disturbance type or time since rehabilitation could be detected. This may well reflect the large variation in the type of disturbance and also the fact that rehabilitated areas were extremely heterogeneous in their composition and stage of rehabilitation.

Table 1 shows the non-indigenous species that

were found during this survey and also during the various components of the surveillance program described by Whittle *et al.* (2013a) and implemented by us. There are 25 confirmed non-indigenous species and seven putative species, whose status is uncertain. All of these species are believed to have been present prior to commencement of the Gorgon Gas Development project. The status of each group was confirmed by consulting the literature, pest databases and by feedback from the relevant specialists for each taxonomic group. The putative species may well be cosmopolitan species that have been spread by natural means, such as aerial plankton in the case of the Collembola species, or may occur in any Australian environment once it is disturbed, as may be the case with the ant *Cardiocondyla nuda*. Others may be synanthropic species whose status as a native to Australia remains a matter of debate, as is the case with the red-backed spider, *Latrodectus hasseltii* (Griffiths *et al.* 2005). Of the confirmed non-indigenous species, several are well-known stored product insects, such as most of the beetles and moths, and a number are associated with buildings and other structures, which is the case for all of the spiders.

### RICHNESS OF THE TERRESTRIAL INVERTEBRATE FAUNA

The combined results of the Pilot, GP and NIS surveys give a total of 1,873 morphospecies of terrestrial invertebrates. If the sites and periods for the Pilot, GP and NIS sampling programs are taken together and analysed for species accumulation by the EstimateS computer package (Colwell 2000; Colwell and Coddington 1994), the Chao2 estimator predicts a total terrestrial invertebrate richness of 2,481 species, indicating that the survey is not complete. A similar analysis of those orders that were sufficiently diverse for the procedure to be reliably performed enables a consideration to be made about the groups that were under-sampled (Table 2). In this case it was only possible to perform the analysis on the GP and NIS data and only on taxa that were diverse enough to analyse; the numbers therefore do not exactly match those from the global analysis. The analysis indicates that most taxa had not been completely sampled by GP and NIS surveys. Notable examples include Acarina (taxonomic verification had not been completed at the time), Mantodea (possible method bias), Neuroptera (reason unknown), Heteroptera (unavailability of taxonomists), Coleoptera (high diversity), Diptera (high diversity) and Hymenoptera (samples initially only identified from one sampling period). However, subsequent sampling has increased the species count, with values for most taxa rising to, or even exceeding, the estimated total of species (Table 2).

TABLE 2 Numbers of morphospecies sampled from the most species-rich groups during the GP and NIS baseline survey and as predicted by the Chao2 estimator, plus the number of species sampled to date. The percentage of predicted species sampled by the baseline survey to date are also shown.

Higher Taxon	Lower Taxon	Species and morpho-species sampled in baseline survey	Chao2 estimate of total species	Percentage of estimated species sampled by GP and NIS survey	Species and morpho-species sampled to date	Percentage of estimated species sampled to date
MOLLUSCA						
Gastropoda	Pulmonata	9	15	60.0	9	60.0

	Hymenoptera	269	498	54.0	373	74.9

TABLE 3

Dichotomous key for new species additions to the baseline (Based on specimens that are mature and of the appropriate sex for identification to species).

1. Specimen aligns with species in the Curtin BWI Reference Collection ..... 2
- Specimen does not align with species in Curtin BWI Reference Collection ..... 3
2. Residence status of species on BWI already known –
  - If only one or two specimens of species in Curtin BWI Reference Collection:
    - specimens bottled or pinned and added to collection
    - Numerous specimens available in Curtin BWI Reference Collection:
      - specimens kept together with bulk specimens in vial and stored in permanent wet collection.
  - Residence status of species on BWI unknown:
    - Taxonomist for Order or Family available and willing to take specimens ..... 4
    - No taxonomist available ..... 5
  - Taxonomist identifies specimen(s) as previously collected on BWI ..... 6
  - Taxonomist identifies specimen(s) as not previously collected on BWI ..... 7
  - Specimen identifiable to species by in-house parataxonomist ..... 9
  - Specimen not identifiable to species (no keys available):
    - specimen designated morphospecies number and stored for future confirmation of species if taxonomist or taxonomic keys become available. Provisionally added to baseline, included in annual report.
  - Specimen is returned to Curtin and incorporated into collection ..... 2
  - Specimen is not returned to Curtin:
    - taxonomist queried for identification notes/photographs if Curtin BWI Reference Collection does not contain a representative specimen
  - Specimen is identifiable to species ..... 8
- Specimen is not identifiable to species (possibly new species) ..... 12
- Any available information is sought on species from taxonomist and from published sources:
  - Species is a known non-native species for Australia:
    - Chevron informed immediately.
    - Species is a known native species for Australia ..... 9
  - Species known from northern Western Australia ..... 10
  - Species not known from northern Western Australia ..... 11
- Species is vagile, disperses easily, and likely to be detected by collection method and sampling regime:
  - most likely naturally dispersed to BWI from mainland. Added to baseline, included in annual report.
  - Species is sedentary and/or difficult to detect:
    - most likely native to BWI but not collected previously. Added to baseline, included in annual report.
  - Species is vagile, disperses easily, and likely to be detected by collection method and sampling regime:
    - most likely human assisted. Chevron informed immediately.
    - Species is sedentary and/or difficult to detect:
      - most likely native to BWI but not collected previously. Added to baseline, included in annual report.
  - Genus/Family known from Australia:
    - species likely to be native to BWI but not collected previously, designated morphospecies number. Added to baseline, included in annual report.
    - Genus/Family not known from Australia ..... 11

## SURVEILLANCE

Based on five exemplar invasive invertebrates species, Barrow Island was classed into three zones of invasion susceptibility. This was based on analyses of potential entry points, establishment and spread of these exemplars onto the island. Risk Zones were identified where the likelihood of entry and suitability of the environment for establishment were medium to high probability. These zones fell predominantly within six sites on the island; these were the Accommodation Camp, Airport, Barge Landing, Horizontal Directional Drilling site, Materials Off-loading Facility and finally the Gorgon Gas Development Footprint. The surveillance methods were chosen from the suite of methods used in the baseline surveys in accordance with suggestions made by a Quarantine Expert Panel. These analyses have been reported in Whittle et al. (2009; 2013b) and Barrett et al. (2010) and are summarised in Whittle et al. (2013a).

Within the first year of construction (2009–2010), after ministerial approval was granted, a preliminary survey was conducted to test the efficacy of the surveillance program (Seismic Survey 2009–2010) and to reinforce the knowledge of established NIS invertebrates on the island (Built Environment Survey 2010; Collembola Survey 2010). This yielded new additions to the baseline species list, as well as hitherto undetected non-indigenous species (Greenslade 2010). Previously undetected NIS were identified as synanthropic species (Table 1) that inhabited the built environment (e.g., some of the stored-products insects) and hence were not

collected in previous trapping efforts (NIS Survey) that focussed on areas external to the buildings.

The surveillance programme is now in its third year of implementation, with a field survey undertaken at the six sites each summer and winter season (March and September). This was based on the significant seasonality observed in the GP survey and to ensure that natural variability in invertebrate populations is adequately sampled. To date, the surveillance has increased the record of indigenous invertebrate species to 2,397. Each additional species collected was scrutinised for its potential to be a NIS and expert advice was sought to assess whether its presence on the island had been assisted by Gorgon's activities. At the time of writing no specimen has been identified as a potential introduction, and new species have either been placed as ones that were not detected in the baseline surveys or as vagrant species from the mainland that are easily transported by strong winds to BWI.

## DISCUSSION

A number of developments have occurred since the 2005–7 surveys, notably further determinations from taxonomists, a dedicated survey of Collembola and the implementation of the surveillance program. Figure 5 shows the accumulation of species through the progression of these developments, reaching a current total of 2,397 as of mid-2013. The slowing of accumulation of species is commensurate with the asymptote calculated by the Chao2 estimator, suggesting that this may be close to the actual value for the island.

One of the issues that the Gorgon Project faces is the determination of whether a newly discovered species on the island is a native species hitherto undocumented for the island or a species that has been introduced as a result of Gorgon related activities. Terrestrial invertebrates are comprised of a variety of life forms and life histories, making them difficult to completely assess during surveys. No matter how many samples or collection methods are employed, a variety of issues may impede the collection of any one species at any one time. Some have cryptic life histories and hence are not readily captured, while others display large variances in seasonal populations and hence may not be captured in one given year or season. Also, Barrow Island is an offshore island less than 60 km from the coast and is in an area that experiences annual cyclonic events. Larger, strong fliers can be assisted by strong winds, or smaller, planktonic forms can drift across the ocean in large enough populations to colonise an island. All these factors make the determination on the native status of a newly encountered species quite difficult. We have

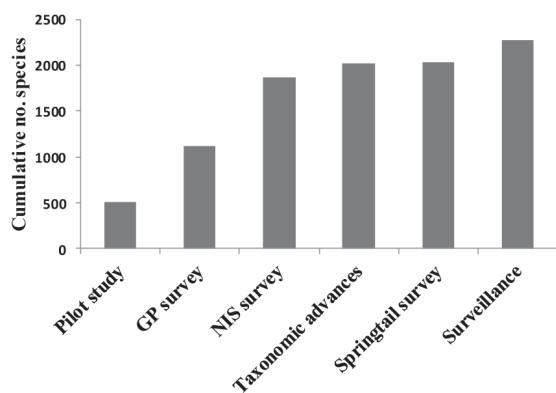

FIGURE 5

Increment in number of morphospecies through the various surveys and taxonomic developments on Barrow Island that have taken place between 2005 and mid-2012.

developed a dichotomous key of questions to aid determining the native status of a species (Table 3).

In terms of duration, range of methods used, and taxonomic breadth, this is probably the most comprehensive terrestrial invertebrate survey ever undertaken in Australia. Whether or not the island's species richness is high or low in comparison with mainland sites is difficult to say. Although surveys exist for the Pilbara and the Southern Carnarvon Basin (George et al. 2011; Burbidge et al. 2000), the sampling methods and taxonomic coverage are not the same. However, our survey does provide important baseline data for the terrestrial invertebrate fauna of an arid Australian island and a Carnarvon Basin ecosystem. This information can be used for environmental monitoring and as a background for future surveillance programs. Yet the fact that the differences in faunal composition between the same months in different years can be as great as the difference between seasons within a given year needs to be taken into account when considering the temporal aspects of the program.

## ACKNOWLEDGEMENTS

The Gorgon Project is operated by an Australian subsidiary of Chevron, Chevron Australia Pty Ltd, and is a joint venture of Chevron Australia Pty Ltd (approximately 47 per cent), ExxonMobil (25 per cent) and Shell (25 per cent), Osaka Gas (1.25 per cent), Tokyo Gas (one per cent) and Chubu Electric Power (0.417 per cent). The authors are grateful to Chevron Australia Pty Ltd for on-island support with logistics, and the Gorgon Project Partners for financial support to undertake the project. Karen Edward, Rebecca Severtson, Tim Lardner, Dr Anita Lyons, Morgan Lythe, Natalie Randall, Brad Scanlon, Adele Scarfone, Dusty Severtson and Callum Smithyman all assisted the project, either in the field and/or in the laboratory.

MANUSCRIPT RECEIVED 10 DECEMBER 2012; ACCEPTED 20 MARCH 2013.

Taxonomic list of species sampled during the GP and NIS surveys and during the subsequent surveillance program. Surveillance includes surveys from the Seismic Study (S1 and S2) and from the commencement of construction (C1–C4). Other collections include additional surveys carried out such as the Collembola Survey and the Built Environment Survey.
